Problem Statement

To build a network intrusion detector, a predictive model capable of distinguishing between bad connections, called intrusions or attacks, and good normal connections [1].

We intend to build the models for binary classification and compare the metrics for attacks and normal connections.

We plan to implement the following additional features for enhancement and learning purpose:

- 1) To model this intrusion detection as a multi-class classifier to detect the type of each intrusion.
- 2) To create a more balanced dataset using down sampling and oversampling.
- 3) To perform feature importance analysis to select top-10 most important features and train model on the selected features to compare performance.
- 4) To model using additional dataset [2].

Methodology

Dataset

The dataset used in this project [1] is a subset of UNSW-NB 15 dataset [3]. The dataset in [1] has 45 features with class label of 0 for normal record and 1 for attack record.

The details of the dataset are as follows

Description	Records	Features
Unprocessed train set	175341	45
Unprocessed test set	82332	45
Preprocessed train set	81173	44
Preprocessed test set	35179	44
Post encoding train set	81173	68
Post encoding test set	35179	67
Final preprocessed train set with common features	81173	66
Final preprocessed test set with common features	35179	66

Table 1: Dataset details

Data preprocessing

The data from test set and train set available at [1] was preprocessed by using the steps below:

- 1) Read .csv data into data frames by marking any 'NA', '?', '-', as NaN.
- 2) Drop all values marked as NaN.
- 3) Drop column 'id'.
- 4) Drop null values.
- 5) Identify numeric and categorical columns
- 6) Perform numeric and categorical encoding on numeric and categorical columns respectively.
- 7) Identify common features between train set and test set
- 8) Drop all columns not common to train set and test set
- 9) Save preprocessed train set and test set for prediction using models.

Models

The preprocessed train and test sets are used to fit the following models for prediction to detect bad connections (intrusions):

- 1) Nearest Neighbor
- 2) Support Vector Machine
- 3) Logistic Regression
- 4) Fully Connected Neural Networks

Model Training and Evaluation

The following steps are generally followed for model training and evaluation:

- 1) Import the class for the model
- 2) Instantiate model
- 3) Fit the model with training data
- 4) Predict the response with test data

Experimental Results and Analysis

The preprocessed train set is used for fitting the models and the preprocessed test set is used for prediction to detect intrusions.

Model Performance Evaluation

The prediction results for each model are as follows:

1) Nearest Neighbor (K=3)

```
Accuracy score: 0.9930071917905569

Table 3: Comparison of neural network after performing hyper parameter tuning

Additional Features

1) Multilabel Classification

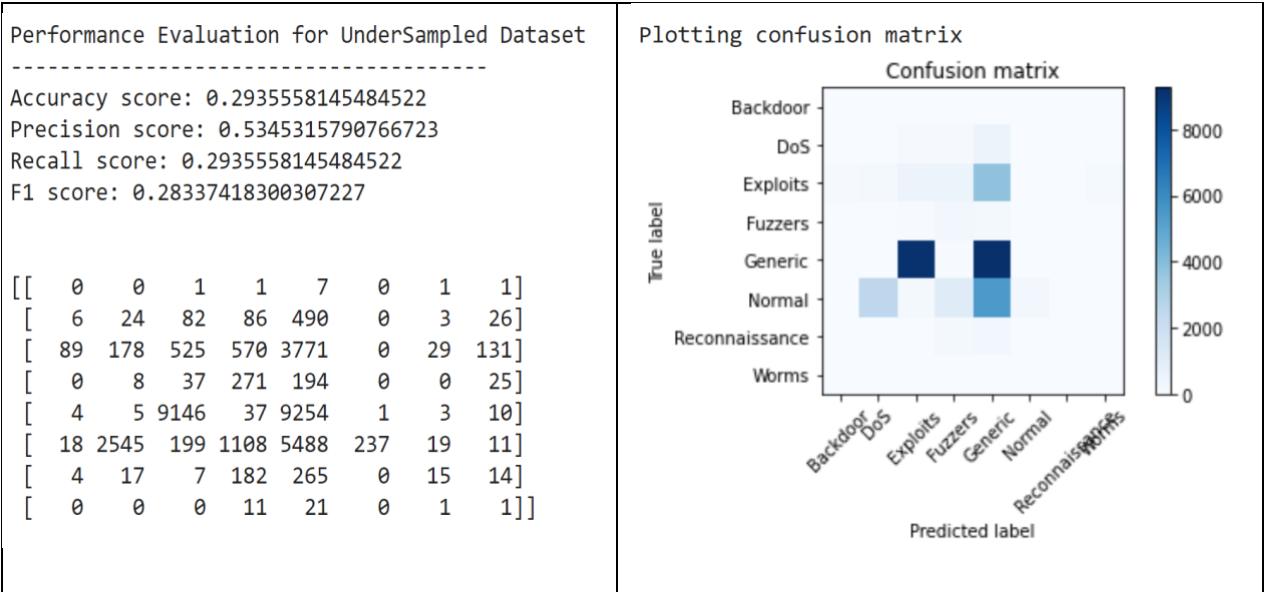

- ‘Attack_cat’ is used as target column which is used to identify type of attack
- Since target column was categorical, it was label encoded and then converted to tensor using to_xy()
- Dataset was unbalanced – More counts for Generic and Normal

2) Over and Under Sampling

- Scikit- Imblearn functions were used to achieve under and oversampling
- Under Sampling – Near Miss
- Over Sampling – Synthetic Minority Over Sampling Technique (SMOTE), Random Sampler
- Over Sampling was better than Under Sampling due to less record count of minority classes

Under Sampling

Table 4: Performance metrics after using oversampling

3) IoT Dataset

- Modeled as binary classification problem with attack as target column
- Dropped all null and missing values
- pkSeqId column was dropped
- Categorical columns were one hot encoded and Numeric columns were normalized
- For 'saddr' and 'daddr' intersection of test and train datasets were taken and the common columns are one hot encoded

Additional Features

2) Feature Importance Analysis

A large number of features can increase the training time for the models [4]. They may also take a large amount of system memory [5]. We use feature selection to reduce the number of features used for training the fully connected neural network.

We use the filter method to compute the relationship between features and the target variable and filter the features based on the computed scores. This method allows us to compute the importance of feature and select the most important features to train the model.

As the output variable for the model is categorical, we have a Classification predictive modeling problem [5]. Based on the input and output variables present in the dataset, we use univariate statistical measures to identify most important features.

The scikit-learn library provides implementation for useful statistical measures [5]. We use ANOVA: `f_classif()` statistical measure based on the output variable of our model [6]. Further, the library also provides methods for filtering the features. We use `SelectKBest` to select top 10 variables.

Task Division and Project Reflection

Task Division

Data Preprocessing	Harshitha, Gargi
Logistic Regression	Harshitha
Nearest Neighbor	Gargi
Support Vector Machine	Gargi
Fully Connected Neural Network and Hyper Parameter Tuning	Harshitha
Additional Features - Multi-class classification problem	Harshitha
Additional Features - Under and Over Sampling	Harshitha
Additional Features - Feature important analysis	Gargi
Additional Features – IoT Dataset	Harshitha

Table 5: Task Division details

Project Reflection

Multiple challenges were encountered during the project implementation which allowed to learn new techniques and tools.

1. **Virtual Collaboration:** Since the project must be carried out virtually, communication and collaboration are challenging. With the help of collaborative tools like Google Colab, Git and Zoom we were able to connect and coordinate better.
2. **Data Preprocessing:** Data Preprocessing is a major portion of any AI or Machine learning. Understanding the nature and context of each column and how we process huge datasets is key to better model performance.
3. **Saving Preprocessed data:** Since AI programs are process intensive, it is better to save preprocessed data to csv and reuse it later instead of preprocessing the data.
4. **Code Reusability:** Data preprocessing and plot lib functions are used across many notebooks. To achieve clean code, the above functions are put in a separate helper file and imported across notebooks rather than having it in each notebook.
5. **Fine tuning hyper parameters for models:** Fine tuning hyper parameters require a lot of permutation and combination to get it right. Changes should be small and only a few parameters must be changed at once step.
6. **Feature importance analysis:** Feature selection can be done in different ways. Identifying and implementing the method suitable for the given type of problem statement is important. Feature selection reduces the model training time and can make significant difference when a large number of features are present in the dataset.
